Abstract

We prove that a $k$-tree can be viewed as a subgraph of a special type of $(k + 1)$-tree that corresponds to a stacked polytope and that these “stacked” $(k + 1)$-trees admit representations by orthogonal spheres in $\mathbb{R}^{k+1}$. As a result, we derive lower bounds for Colin de Verdière’s $\mu$ of complements of partial $k$-trees and prove that $\mu(G) + \mu(\overline{G}) \geq |G| - 2$ for all chordal $G$.

Yves Colin de Verdière’s graph invariant $\mu$ is defined as the maximum nullity over a special class of real symmetric matrices [3]. Among its many interesting properties are that $\mu$ is minor monotone and $\mu(G) \leq 3$ if and only if $G$ is planar. These properties are collected in a recent survey by László Lovász [13] based on an earlier paper with Hein van der Holst and Alexander Schrijver [22].
Andrew Kotlov, Lovász, and Santosh Vempala showed close connections between \( \mu \) and certain geometric representations of graphs, including vector representations and sphere representations [11]. They also conjectured that \( \mu(G) + \mu(\overline{G}) \geq |G| - 2 \) for all graphs \( G \). Recently, results by John Sinkovic and van der Holst [20] on another parameter defined by Colin de Verdière\(^1\) for complements of partial \( k \)-trees has allowed progress on the similar inequality [1] for that parameter.\(^2\)

We obtain lower bounds for \( \mu \) of complements of partial \( k \)-trees. In particular, we obtain one bound for general \( k \)-trees and another slightly better one for \( k \)-trees that correspond to stacked polytopes. The study of these “stacked” \( k \)-trees is also suggested by recent calculations of \( \mu \) for chordal graphs by Shaun Fallat and the first author [6], which in turn were based on similar patterns appearing in the study of \( \mu \) for split graphs by Felix Goldberg and Abraham Berman [7]. We use the results and connections established by Kotlov, Lovász, and Vempala in order to prove these lower bounds. Finally, we combine our new lower bounds with the chordal calculations to prove that \( \mu(G) + \mu(\overline{G}) \geq |G| - 2 \) for all chordal \( G \).

Besides the work already cited, polytopes and sphere and vector representations have featured prominently in other recent work on \( \mu \). In particular, Ross Kang, Lovász, Tobias Müller, and Edward Scheinerman used

\(^1\)This other parameter is often denoted by \( \nu \), but we will follow Kotlov, Lovász, and Vempala in giving \( \nu \) a different meaning, one related to \( \mu \), in this paper.

\(^2\)For a number of similar parameters defined using the maximum nullity over a class of matrices, the corresponding inequality has been called the “graph complement conjecture” for that parameter, and these inequalities are examples of more general “Nordhaus-Gaddum-type” results and conjectures.
sphere representations by tangent spheres (coin representations) and properties of \( \mu \) for planar graphs to study dot product representations [9]. As for polytopes, Ivan Izmestiev showed that if \( G \) is the 1-skeleton of a convex \( d \)-polytope, then \( \mu(G) \geq d \) [8]. In light of his result, a natural follow-up to our work would be to consider sphere representations for such graphs.

In Section 1 we introduce \( k \)-trees and stacked \( k \)-trees. In Section 2 we define \( \mu \) and detail how \( \mu \) is related to vector and sphere representations. In Section 3 we prove our main results by combining sphere representations and stacked \( k \)-trees.

1 Stacked \( k \)-Trees

A clique is a subgraph isomorphic to the complete graph \( K_n \) on \( n \) vertices for some \( n \) (note that we do not assume a clique to be maximal). A vertex \( v \) of a graph is simplicial if it, together with its neighbors, \( N(v) \), form a clique. A graph is chordal if it has no induced cycles of length at least four. All chordal graphs have at least one simplicial vertex [4].

A tree decomposition of a graph \( G = (V, E) \) consists of a tree \( T \) and a family of subsets of vertices of \( G \), \( \{X_i\} \), one for each vertex of \( T \), such that

- \( \bigcup_i X_i = V \);
- if \( uv \in E \) there exists a vertex \( i \) of \( T \) such that \( u \in X_i \) and \( v \in X_i \); and
- for all vertices \( i, j, \) and \( k \) of \( T \), if \( j \) is on the path from \( i \) to \( k \), then \( X_i \cap X_k \subseteq X_j \).

\[ \text{For interested readers, Lovász also has a helpful survey of many types of geometric graph representations [15] as an update of a paper with Katalin Vesztergombi [16].} \]
The width of a tree decomposition is one less than the size of a largest $X_i$. The treewidth $\text{tw}(G)$ of $G$ is the minimum width over all tree decompositions of $G$.

A $k$-tree is a (chordal) graph constructed inductively by starting with a complete graph on $k + 1$ vertices and connecting each new vertex to the vertices of an existing clique on $k$ vertices. The maximal cliques of a $k$-tree are all size $k + 1$ [18].

A graph that is a subgraph of a $k$-tree is a partial $k$-tree. The treewidth of a graph $G$ can also be characterized as the smallest $k$ such that $G$ is a partial $k$-tree [2].

For vertices $x$ and $y$ of a graph $G$, an $x,y$-separator is a subset $S$ such that $x$ and $y$ are in different connected components of $G - S$. A separator is a subset $S$ of $G$ such that $G - S$ has more connected components than $G$ does. Chordal graphs are those graphs whose minimal separators are cliques [5]. It is straightforward that any minimal $x,y$-separator of a subgraph $S$ of $G$ is contained in a minimal $x,y$-separator of $G$.

**Theorem 1.1** ([19, Theorem 1.1]). A graph $G$ is a $k$-tree if and only if $G$ is connected, $G$ has a $k$-clique but no $k + 2$ clique, and every minimal $x,y$-separator of $G$ is a $k$-clique.

A $k$-simplex is a $k$-dimensional convex hull of $k + 1$ points. Stacked polytopes are formed by starting from a simplex and then repeatedly gluing simplices onto the faces of the polytope. A $k$-tree is the 1-skeleton of a stacked polytope if and only if no three $(k + 1)$-vertex cliques have $k$ vertices in common [10].
If $H$ is a clique on $n$ vertices of a graph $G$, we define the degree of $H$ in $G$ to be the number of distinct $n+1$ cliques of $G$ of which $H$ is a subgraph (note this definition agrees with the usual definition for the degree of a single vertex). A clique of degree one will be called pendant, and a clique of degree zero is maximal. Using these definitions, a $k$-tree is the graph of a stacked polytope if and only if each $k$-clique has degree at most two. We will call a chordal graph with treewidth $k$ stacked if each $k$-clique has degree at most two.

**Lemma 1.2.** If $T$ is a stacked $k$-tree, then each clique on at most $k-1$ vertices is contained in at least two pendant $k$-cliques of $T$.

*Proof.* Fix a value for $k$. We will prove that each $(k-1)$-clique is contained in exactly two pendant $k$-cliques, and the result will follow from the fact that each clique on at most $k-1$ vertices is contained in a $(k-1)$-clique.

The result is true for $K_{k+1}$ since every $k$-clique is pendant. Assume the result is true for all stacked $k$-trees on $n \geq k+1$ vertices and let $T$ be a stacked $k$-tree on $n+1$ vertices. Let $v$ be a simplicial vertex of $T$. Then the induction hypothesis applies to $T - v$ and $N(v)$ is the only $k$-clique whose degree differs in $T - v$ and $T$. Also, in $T - v$, each $(k-1)$-clique in $N(v)$ is contained in at least two pendant $k$-cliques, one of which is $N(V)$. In $T$, each $(k-1)$-clique $C$ of $N(v)$ can no longer count $N(v)$ as a pendant $k$-supergraph, however, $C$ is now contained in the pendant $k$-clique $v \cup C$. Note that each $k$-clique of $T$ that contains $v$ is pendant. So, those $(k-1)$-cliques in $T$ that are not subgraphs of $T - v$, contain $v$ and are
therefore in two pendant $k$-cliques, namely, $\{v, x\} \cup C$ and $\{v, y\} \cup C$ where $N(V) - C = \{x, y\}$.

\[ \square \]

**Proposition 1.3.** Suppose that $G$ is a chordal graph with $k \leq \text{tw}(G) \leq k + 1$. If $\text{tw}(G) = k + 1$, suppose further that $G$ is stacked. Then there exists a stacked $(k + 1)$-tree $H$ such that $G$ is a subgraph of $H$.

**Proof.** Fix a value for $k$. If $G$ has at most $k + 2$ vertices, then $H = K_{k+2}$ suffices. Assume next that $G$ has more than $k + 2$ vertices and that the result holds for all graphs on fewer vertices.

If $G$ is a $(k + 1)$-tree, we are done. Suppose $G$ is not a $(k + 1)$-tree. If $\text{tw}(G) = k$, then since $G$ is chordal, $G$ has a minimal separator on at most $k$ vertices. If $\text{tw}(G) = k + 1$, by Theorem 1.1 $G$ has a minimal $x, y$-separator, and thus a minimal separator, on at most $k$ vertices. Thus $G$ can be written as the union of two strictly smaller chordal subgraphs $G_1$ and $G_2$ where $S = G_1 \cap G_2$ is a clique on at most $k$ vertices and there are no edges between $G_1 - S$ and $G_2 - S$ in $G$. By the induction hypothesis, there exist stacked $(k + 1)$-trees $H_1$ and $H_2$ containing $G_1$ and $G_2$, respectively. Let $S_1$ and $S_2$ denote the copies of $S$ in $G_1$ and $G_2$, respectively.

For each $i$, add $k + 1 - |S| > 0$ new vertices to $H_i$ in the following way: make each new vertex, by Lemma 1.2, adjacent to a pendant $(k + 1)$-clique including both $S_i$ and the previously added vertices. The result will be a new graph $H'_i$ with a new pendant $(k + 1)$-clique $S'_i$ consisting of the new vertices and $S_i$. Let $H$ be the union of $H'_1$ and $H'_2$ along $S'_1$ and $S'_2$ preserving the identification of $S_1$ and $S_2$. 

6
By construction and since $S'_1$ and $S'_2$ were pendant, $H$ is a stacked $(k + 1)$-tree containing $G$. 

A linear $k$-tree is a $k$-tree that is either complete or that has exactly two vertices with degree $k$. The proper pathwidth of a graph $G$ is the smallest $k$ such that $G$ is a subgraph of a linear $k$-tree. One might hope that a result similar to Proposition 1.3 is true for linear $k$-trees as well. In general, however, $k$-trees (even 1-trees) can have arbitrarily large proper pathwidth [21], and thus in general cannot be embedded in linear $(k + 1)$-trees.

For each $k \geq 1$, let $T_k$ be the unique infinite $k$-tree where each $k$-clique has degree two.

**Proposition 1.4.** Each finite stacked $k$-tree is a subgraph of $T_k$.

**Proof.** The result is clearly true for $K_{k+1}$. Let $G$ be a stacked $k$-tree on $k + 2$ or more vertices, and assume the result holds for all such graphs on one fewer vertex. Let $v$ be a simplicial vertex of $G$. By the induction hypothesis, $G - v$ is a subgraph of $T_k$. Since $G$ is stacked and $|G| > k + 1$, the vertices of $N(v)$ have exactly two common neighbors in $G$ and exactly one common neighbor in $G - v$. Thus the vertex of $T_k$ that is adjacent to all the vertices of $N(v)$ but not part of the image of $G - v$ may be identified with $v$. 

2 Vector and Sphere Representations

In this section, we present $\mu$ and a parameter $\nu$ associated with vector and sphere representations.
For a simple graph (no loops or multiple edges) $G = (V, E)$ on vertices $1, 2, \ldots, n$, the Colin de Verdière number of $G$, $\mu(G)$, is the maximum corank among all symmetric $n \times n$ matrices $M = [m_{ij}]$ satisfying the following properties:

M1: $m_{ij} < 0$ if $ij \in E$ and $m_{ij} = 0$ if $ij \notin E$ (diagonal entries are not restricted); 

M2: $M$ has exactly one negative eigenvalue; and

M3: If $X = [x_{ij}]$ is a symmetric $n \times n$ matrix with zero diagonal such that $x_{ij} = 0$ for $ij \in E$ and $MX = 0$, then $X = 0$.

Condition M3 is often called the Strong Arnold Property or Strong Arnold Hypothesis.

For the same graph $G$, let $\nu(G)$ be the smallest dimension $d$ such that there exists a vector labeling $\{u_i\}_{i \in V}$ in $\mathbb{R}^d$ that satisfies the following conditions:

U1: for $i \neq j$, the dot product $u_i \cdot u_j = 1$ if $ij \in E$ and $u_i \cdot u_j < 1$ if $ij \notin E$ (so $u_i \cdot u_i$ is not explicitly restricted); and

U2: if $X = [x_{ij}]$ is a symmetric $n$-by-$n$ matrix such that $x_{ij} = 0$ for $ij \notin E$ and $\sum_j x_{ij}u_j = 0$ for every node $i$, then $X = 0$.

We will call such a labeling a vector representation\(^4\) of $G$ [17], and $\nu$ is related to $\mu$ by the following theorem:

\(^4\)This type of vector representation is similar to a dot product representation, which requires a modified form of the first condition ($u_i \cdot u_j \geq 1$ if $ij \in E$) but does not require the second condition. Orthogonal vector representations, such as those famously used in Lovasz’s calculation of the Shannon capacity of the cycle $C_5$ [14], are significantly different and are more closely related to the other Colin de Verdière parameter.
Theorem 2.1 ([11, Theorem 3.3]). For every graph $G$ different from $K_2$, $\nu(G) = n - \mu(G) - 1.$

Given $(d - 1)$-spheres $S_1$ and $S_2$ in $\mathbb{R}^d$, define the function

$$a(S_1, S_2) = \frac{\rho^2 - (r_1 + r_2)^2}{\rho^2 - (r_1 - r_2)^2}$$

where $r_1$ and $r_2$ are the respective radii and $\rho$ is the distance between the centers of $S_1$ and $S_2$. Then $a(S_1, S_2) = a(S_2, S_1)$, and $a(S_1, S_2)$ is preserved by conformal mappings $\mathbb{R}^d \to \mathbb{R}^d$. A similar definition for caps in $S^d$ (spheres together with one of the two regions in $S^d$ that they bound) means that $a(S_1, S_2)$ is also preserved by conformal mappings $\mathbb{R}^d \to S^d$ [11, p. 502].

If $S_1$ and $S_2$ intersect at an angle $\alpha$, then $\rho^2 = r_1^2 + r_2^2 - 2r_1r_2 \cos \alpha$. Thus $S_1$ and $S_2$ are orthogonal spheres, which we will denote by $S_1 \perp S_2$, if and only if $a(S_1, S_2) = -1$ if and only if $\rho^2 = r_1^2 + r_2^2$.

An orthogonal sphere representation of a graph $G = (V, E)$ in $\mathbb{R}^d$ is a labeling of each vertex $i$ with a $(d - 1)$-dimensional sphere $S_i$ so that, for $i \neq j$, $a(S_i, S_j) = -1$ if $ij \in E$ and $a(S_i, S_j) > -1$ if $ij \notin E$. Orthogonal cap representations in $S^d$ are defined similarly, and, by the remark above, given an orthogonal sphere labeling of $G$ in $\mathbb{R}^d$, one can project each sphere into $S^d$ (chosen large enough so that no interior of a sphere is mapped to a hemisphere or more) [11, p. 503]. Moreover, an orthogonal cap representation of a graph in $S^d$ yields a vector labeling of $G$ in $\mathbb{R}^{d+1}$ by associating each cap with the center of the unique sphere in $\mathbb{R}^{d+1}$ that is orthogonal to the unit sphere and whose intersection with $S^d$ (viewed as the unit sphere) is the cap. Thus
**Theorem 2.2** ([11, Lemma 6.2]). If a graph $G$ has an orthogonal sphere representation in $\mathbb{R}^d$, then there exists a vector labeling of $G$ in $\mathbb{R}^{d+1}$ satisfying condition U1.

**Proposition 2.3.** Let $G$ be a $k$-tree. Suppose that a vector labeling $\{u_i\}$ of $G$ satisfies condition U1 and the vectors corresponding to the vertices of any clique of $G$ are linearly independent. Then $\{u_i\}$ is a vector representation of $G$.

**Proof.** The result is true for a graph on one vertex as the corresponding vector must be nonzero. Suppose the result holds for $k$-trees on $n$ vertices and let $G$ be a $k$-tree with $n + 1$ vertices. Let $X = [x_{ij}]$ be a symmetric $n$-by-$n$ matrix such that $x_{ij} = 0$ for $ij \notin E$ and $\sum_j x_{ij}u_j = 0$ for every vertex $i$. Let $v$ be a simplicial vertex of $G$, so that the neighbors of $v$ form a clique, and thus the vectors corresponding to those vertices are linearly independent by assumption. Therefore,

$$\sum_j x_{vj}u_j = \sum_{v \in E} x_{vj}u_j = 0$$

implies that $x_{vj} = 0$ for all $j$. Since $X$ is symmetric, both the row and column of $X$ corresponding to $v$ are zero. Applying the induction hypothesis to $G - v$, $\{u_i\}_{i \neq v}$, and the submatrix of $X$ obtained by deleting the row and column corresponding to $v$, we may conclude that $X = 0$, as desired. \qed

**Corollary 2.4.** Let $\overline{G}$ be a $k$-tree other than $K_2$. If $\{u_i\}$ is a vector labeling in $\mathbb{R}^d$ of $\overline{G}$ satisfying condition U1 such that $\|u_i\| > 1$ for each $i$, then $\mu(G) \leq n - d - 1$. 

10
Proof. The Gram matrix of the $u_i$ corresponding to a clique $C$ in $\overline{G}$ can be written as the sum of a positive definite diagonal matrix and the (positive semidefinite) matrix of all ones, thus has full rank, and so the $u_i$ corresponding to $C$ are linearly independent. The result now follows from Theorem 2.2 and Proposition 2.3.

3 Main Results

We are now in a position to bound $\mu$ for complements of $k$-trees by constructing orthogonal sphere representations.

Lemma 3.1. Let $S_1$ and $S_2$ be nontrivial $n$-spheres in $\mathbb{R}^{n+1}$ and let $P$ be a copy of $\mathbb{R}^k$ in $\mathbb{R}^{n+1}$ for some $k \geq 1$ such that $S_1 \cap P$ and $S_2 \cap P$ are nontrivial. Suppose that either $S_1 \perp S_2$ or $(S_1 \cap P) \perp (S_2 \cap P)$. Then $S_1 \perp S_2$ and $(S_1 \cap P) \perp (S_2 \cap P)$ if and only if $P$ contains either the center of $S_1$ or the center of $S_2$.

Proof. Let $r_1$, $r_1'$, $r_2$, and $c_1$, $c_1'$, $c_2$, and $c_2'$ be the radii and centers of $S_1$, $S_1 \cap P$, $S_2$, and $S_2 \cap P$, respectively. Then $d_i = \|c_i - c_i'\|$ gives the distance from $c_i$ to $P$, and we have $r_i^2 = d_i^2 + (r_i')^2$ for each $i$. Similarly, using $\rho = \|c_1 - c_2\|$ and $\rho' = \|c_1' - c_2'\|$, $\rho^2 = (d_1 - d_2)^2 + (\rho')^2$, so that

$$\rho^2 - r_1^2 - r_2^2 = (d_1 - d_2)^2 + (\rho')^2 - (r_1')^2 - d_1^2 - (r_2')^2 - d_2^2$$

$$= (\rho')^2 - (r_1')^2 - (r_2')^2 - 2d_1d_2.$$

Thus if either $S_1 \perp S_2$ or $(S_1 \cap P) \perp (S_2 \cap P)$, the other can only happen if either $d_1$ or $d_2$ is zero. \qed
Lemma 3.2. Given orthogonal $n$-spheres $S_1$ and $S_2$ in $\mathbb{R}^{n+1}$, $S_1 \cap S_2$ is an $(n - 1)$-sphere that lies in a unique $n$-dimensional hyperplane $H$. A third $n$-sphere $S_3$ is orthogonal to both $S_1$ and $S_2$ if and only if the center of $S_3$ lies on $H$ and $S_1 \cap S_2$ and $S_3 \cap H$ are orthogonal $(n - 1)$-spheres.

Proof. Since $S_1$ and $S_2$ are orthogonal, $S_1 \cap S_2$ is nonempty and does not consist of a single point. Thus $S_1 \cap S_2$ is an $(n - 1)$-sphere lying in a unique hyperplane $H$ of dimension $n$. Since $S_1 \cap H = S_2 \cap H = S_1 \cap S_2$, the result follows by applying Lemma 3.1 to $S_3$ and $S_1$ and to $S_3$ and $S_2$. \hfill $\square$

Lemma 3.3. Given $n$ mutually orthogonal $(n - 1)$-spheres $S_1, \ldots, S_n$ in $\mathbb{R}^n$, $\bigcap_i S_i$ consists of two points. Let $L$ be the line through those two points and let $U$ be the union of the interiors of the spheres. Given any point $p$ on $L \setminus \text{cl} U$, there exists an $(n - 1)$-sphere, $S(p)$, that is orthogonal to each
$S_i$ and has center $p$. Furthermore, the radius of $S(p)$ approaches 0 as $p$ approaches $U$ along $L$.

Proof. We use induction on $n$. In $\mathbb{R}$, a single 0-sphere consists of two points $c \pm r$, and given any point $p$ outside of the interval $[c - r, c + r]$ there is a positive solution to $r^2_1 = (c - p)^2 - r^2$. Assume the result is true for all $n \leq k$ for some $k$, and suppose $n = k + 1$. Suppose we have mutually orthogonal $k$-spheres $S_1, \ldots, S_{k+1}$ in $\mathbb{R}^{k+1}$. By Lemma 3.2, $S_k \cap S_{k+1}$ defines a hyperplane $H \cong \mathbb{R}^k$. For each $i \leq k$, let $R_i = S_i \cap H$. Note that $R_k = S_k \cap S_{k+1}$ and therefore $\bigcap \{R_i : i \leq k\} = \bigcap \{S_j : j \leq k + 1\}$. Again by Lemma 3.2, $R_1, \ldots, R_k$ are mutually orthogonal $(k - 1)$-spheres in $H$. By the induction hypothesis, $\bigcap \{R_i : i \leq k\}$ consists of two points. Let $L$ and $U$ be as in the statement of the Lemma (for the $S_i$). By definition, $L \subset H$. Let $p \in L \setminus \text{cl} \ U = L \setminus \text{cl} \ (U \cap H)$. Again by the induction hypothesis, there exists a $k - 1$-sphere $S'(p)$ with center at $p$ such that $S'(p)$ is orthogonal to each $R_i$. Let $S(p)$ be the $k$-sphere with the same center and radius as $S'(p)$. Denote the radii of $S(p)$ and $S_1$ as $r_p$ and $r_1$ respectively. Let $c_1$ be the center of $S_1$ and let $\rho_p$ be the distance between $p$ and $c_1$. Since $S(p)$ and $S_1$ are orthogonal $r_p^2 + r_1^2 = \rho_p^2$. Hence as $p$ approaches $U$ along $L$, $p$ approaches $S_1$, $\rho_p$ approaches $r_1$, and therefore $r_p$ approaches 0. 

Proposition 3.4. Each $T_k$ has an orthogonal sphere representation in $\mathbb{R}^k$ with spheres of positive radius.

Proof. We construct a nested sequence of representations, $(S'_k)$, of finite subtrees of $T_k$ inductively and then we set $S_k = \bigcup_{i=1}^{\infty} S'_k$. Let $T_k^0 = K_{k+1}$ and let $T_k^{i+1}$ be the graph obtained from $T_k^i$ by adding a new vertex to each
pendant \( k \)-clique. Assuming we have defined \( S^i \), for a vertex \( v \) of \( T^i \) let \( s(v) \) be the corresponding sphere.

Represent \( T^0 \) by starting with a set, \( S^0 \), of \( k + 1 \) mutually orthogonal nontrivial \((k - 1)\)-spheres in \( \mathbb{R}^k \). Note that for each pendant \( k \)-clique \( C \) of \( T^0 \) there exists a point \( p(C) \) of \( \cap_{v \in C} s(v) \) that is not in \( \cup_{v \notin C} \operatorname{cl} s(v) \). Note also that distinct elements of \( S^0 \) are either orthogonal or disjoint.

Assume that we have a representation \( S^i \) for \( T^i \) with these two properties. Then for each pendant clique \( C \) there exists an open neighborhood \( U(C) \) of \( p(C) \) that does not intersect \( \bigcup_{v \notin C} \operatorname{cl} s(v) \). We may choose the \( U(C) \) to be pairwise disjoint. By Lemma 3.3, for each \( j \) choose a new sphere \( S_j \) inside \( U(C_j) \) orthogonal to each element of \( \{ s(v) : v \in C_j \} \). Let \( S^i = S^i_k \cup \{ S_j \} \).

By construction and by our choices of the \( U(C_j) \), \( S^i_{k + 1} \) represents \( T^i_{k + 1} \), and two distinct elements of \( S^i_{k + 1} \) are either orthogonal or disjoint. Let \( C \) be a pendant \( k \)-clique of \( T^i_{k + 1} \) and let \( w \notin C \) be the additional vertex of the maximal clique containing \( C \). By Lemma 3.3, \( \cap_{v \in C} s(v) \) consists of two points, one of which, \( p(C) \), does not lie in the interior of \( s(w) \). By our choice of \( U((C \cap T^i_k) \cup \{ w \}) \), \( p(C) \) is not in \( \operatorname{cl} s(v) \) for any \( v \) not in \( C \).

**Corollary 3.5.** If \( G \) is the complement of a partial \( k \)-tree, then \( \mu(G) \geq n - k - 3 \).

**Proof.** By assumption, \( \overline{G} \) is a subgraph of a \( k \)-tree \( \overline{G'} \). Thus \( \overline{G'} \) is a subgraph of a stacked \((k + 1)\)-tree, \( \overline{H} \), by Proposition 1.3. If \( H \neq \overline{K}_2 \), then \( \mu(H) = n - v(\overline{H}) - 1 \), by Theorem 2.1. If \( H = \overline{K}_2 \), then \( \mu(H) = 1 \geq -2 \) [13, Example 2.7]. By Proposition 1.3, Proposition 1.4, and Proposition 3.4, \( \overline{H} \) has an orthogonal
sphere representation in $\mathbb{R}^{k+1}$. By Theorem 2.2 and Proposition 2.3, $\overline{H}$ has a vector representation in $\mathbb{R}^{k+2}$. Thus $\nu(\overline{H}) \leq k + 2$. \hfill \Box

**Corollary 3.6.** If $G$ is the complement of a subgraph of a stacked $k$-tree, then $\mu(G) \geq n - k - 2$.

**Proof.** The proof is the same as that of Corollary 3.5 except now $\overline{H}$ may be assumed to be stacked. \hfill \Box

**Theorem 3.7** ([6, Theorem 5.7]). If $G$ is a stacked chordal graph, then $\mu(G) = \text{tw}(G)$. If $G$ is a chordal graph that is not stacked, then $\mu(G) = \text{tw}(G) + 1$.

**Proposition 3.8.** For a chordal graph $G$, $\mu(G) + \mu(\overline{G}) \geq n - 2$.

**Proof.** Let $\text{tw}(G) = k$. Then $G$ is a partial $k$-tree. If $G$ is stacked, then $\mu(G) = k$ by Theorem 3.7 and $\mu(G) \geq n - k - 2$ by Corollary 3.6. If $G$ is
not stacked, then $\mu(G) = k + 1$ by Theorem 3.7 and $\mu(G) \geq n - k - 3$ by Corollary 3.5.
